export options enable users to examine collected flight data using commonly available analytical tools.

For visualization, the project employs a browser-based dashboard integrated with Leaflet maps. The dashboard displays aircraft positions in near real time and allows users to observe movement patterns through continuously updated trajectory paths. Recent trajectory points are preserved to provide a visual representation of flight routes, improving situational awareness and enabling users to understand aircraft movement over time. The system also supports prediction-oriented entries when sufficient recent observations are available, providing an estimated continuation of aircraft trajectories for monitoring purposes.

A key focus of the project is simplicity, portability, and practical usability. The architecture is designed to operate efficiently on standard computing systems without requiring complex infrastructure. By combining data acquisition, message decoding, storage, export capabilities, and map-based visualization into a single platform, the project demonstrates a complete surveillance data processing pipeline. The developed system successfully converts low-level ADS-B transmissions into human-readable operational information that can be used for educational purposes, aviation research, flight trajectory analysis, and surveillance system studies.

Overall, the project highlights the practical application of web technologies, database systems, and data processing techniques in the aviation domain. It provides a functional framework for aircraft monitoring while offering opportunities for future enhancements such as advanced trajectory prediction, anomaly detection, integration with additional ADS-B receivers, and large-scale cloud-based deployment.
